3. Q2: Broadcast Race
4. Q3: Distributed Dot Product
5. Q4: Prime Finder
6. Q5: Perfect Number Finder
7. What I Learned

System Configuration

Component	Details
CPU	Intel Core i7-14700HX (20 cores, 28 threads)
Architecture	x86_64
L3 Cache	33 MiB
OS	Fedora 43 (Linux 6.19.11)
MPI	OpenMPI 5.0.8

Component	Details
Compiler	gcc 15.2.1 via mpicc
Optimization	-O3
Processes Tested	1, 2, 4, 8, 16

Q1: DAXPY with MPI

Problem

Implement DAXPY operation `X[i] = a*X[i] + Y[i]` on vectors of size 2^16 using MPI. Measure speedup vs sequential.

Approach

- Rank 0 initializes vectors, distributes via `MPI_Scatter`
- Each process computes DAXPY on local chunk

- Results gathered via `MPI_Gather`
- 50 repeats for stable timing

Results

Processes	Sequential	Parallel	Speedup	Efficiency
1	23 us	41 us	0.55x	55.0%
2	23 us	59 us	0.39x	19.6%
4	21 us	72 us	0.29x	7.3%
8	41 us	129 us	0.32x	4.0%

All results: **[PASS]** (max error = 0.00)

Analysis

DAXPY at 65536 elements is **too small** for MPI to help. Communication overhead (Scatter + Gather) dominates the ~23 microsecond computation. This is a classic demonstration of Amdahl's Law: when communication cost exceeds compute cost, adding processes makes it slower. MPI shines on problems where computation significantly outweighs communication — not on 0.5 KB of work per process.

Q2: Broadcast Race

Problem

Compare linear broadcast (for-loop of `MPI_Send`) vs built-in `MPI_Bcast` for 10 million doubles (~80 MB).

Approach

- **MyBcast**: Rank 0 sends to each rank sequentially — O(p) time
- **MPI_Bcast**: Uses tree-based algorithm — O(log p) time
- 5 repeats, barrier-synchronized

Results

Processes	MyBcast (linear)	MPI_Bcast (tree)	Speedup
2	0.0105 s	0.0080 s	1.32x
4	0.0302 s	0.0225 s	1.35x
8	0.0701 s	0.0194 s	3.61x
16	0.2359 s	0.0714 s	3.30x

Analysis

MyBcast time grows **linearly** with processes — Rank 0 must send 80 MB to each rank one by one. MPI_Bcast uses **tree distribution** (Rank 0 sends to Rank 1, then both send to Rank 2 and 3, etc.), giving O(log p) scaling. At 8 processes, MPI_Bcast is 3.6x faster. The advantage grows with process count because linear sends create a bottleneck at the root.

Q3: Distributed Dot Product

Problem

Compute dot product of two 500-million-element vectors using `MPI_Bcast` + `MPI_Reduce`. Calculate speedup and efficiency per Amdahl's Law.

Approach

- Rank 0 broadcasts scaling multiplier via `MPI_Bcast`
- Each process generates its local chunk (no scatter needed — saves memory)
- Local dot product computed, then `MPI_Reduce` with `MPI_SUM`

Results

Processes	Time (s)	Speedup	Efficiency
1	0.3586	1.00x	100.0%
2	0.2039	1.76x	87.9%
4	0.1383	2.59x	64.8%
8	0.1106	3.24x	40.5%

All results: **[PASS]** (correct result = 1,000,000,000)

Analysis

Speedup is **sub-linear** — 3.24x on 8 processes instead of ideal 8x. Reasons:

1. **Memory bandwidth saturation**: dot product is memory-bound (1 FLOP per 2 loads). Multiple processes compete for shared memory bus
2. **Communication overhead**: MPI_Reduce adds latency
3. **Amdahl's Law**: serial fraction (init, reduction) limits max speedup

Efficiency drops from 88% (2 proc) to 41% (8 proc) — typical for memory-bound workloads on shared-memory systems.

Q4: Prime Finder (Master-Slave)

Problem

Find all primes up to 100,000 using master-slave MPI pattern.

Approach

- **Master (Rank 0)**: distributes numbers to test, collects results
- **Slaves**: receive number, test primality, return result (positive = prime, negative = not prime)
- Dynamic load balancing — master sends next number to whichever slave finishes first

Results

Processes	Time (s)	Primes Found
2	0.0459	9592
4	0.0281	9592
8	0.0319	9592

All results: **[PASS]** (expected 9592 primes below 100,000)

Analysis

4 processes is optimal here. At 8 processes, performance degrades slightly because: the master becomes a bottleneck (processing requests from 7 slaves), communication overhead per number exceeds primality test cost for small numbers. The master-slave pattern works best when each work unit is computationally expensive relative to message passing.

Q5: Perfect Number Finder (Master-Slave)

Problem

Find all perfect numbers (where sum of proper divisors equals the number) up to 100,000.

Approach

Same master-slave pattern as Q4, but testing for perfect number property instead. Each slave sums divisors of received number.

Results

Processes	Time (s)	Perfect Numbers
2	0.0727	6, 28, 496, 8128
4	0.0350	6, 28, 496, 8128
8	0.0338	6, 28, 496, 8128

All results: **[PASS]** (found all 4 perfect numbers below 100,000)

Analysis

Better scaling than primes (Q4) because divisor-sum computation is heavier per number — more compute per message. 4 and 8 processes perform similarly, suggesting master bottleneck again. Perfect numbers are extremely rare (only 4 below 100,000), so most work units return negative results.

Performance Dashboard

What I Learned

1. **MPI communication cost is real**: DAXPY showed that for small problems, Scatter/Gather overhead alone can be 3-5x the computation time. MPI only helps when work-per-process significantly exceeds message latency.

2. **Tree vs linear broadcast matters at scale**: MPI_Bcast's tree algorithm is 3.6x faster at 8 processes for 80 MB. Linear broadcast creates a root bottleneck — O(p) vs O(log p).

3. **Memory-bound vs compute-bound**: Dot product (memory-bound) showed sub-linear speedup on shared memory. Memory bandwidth is shared across processes, limiting parallel gains.

4. **Master-slave has a built-in bottleneck**: Both prime and perfect number finders showed diminishing returns past 4 processes. Single master cannot dispatch fast enough when work units are cheap.

5. **Local generation beats Scatter for large data**: In Q3, having each process generate its own chunk locally instead of scattering from root saved both memory and communication time.

Compilation & Execution

```
# Build everything
make all

# Run individual exercises
make run-q1    # DAXPY with 1,2,4,8 processes
make run-q2    # Broadcast race with 2,4,8,16 processes
make run-q3    # Dot product with 1,2,4,8 processes
make run-q4    # Primes with 2,4,8 processes
make run-q5    # Perfect numbers with 2,4,8 processes

# Run all
make run-exercises

# Clean
make clean
